StableSave

STABLECOIN YIELD INTELLIGENCE + SOLANA VAULT PROTOTYPE

Know the risk before you chase the yield.

A simpler way to compare stablecoin yield opportunities, understand risk, and see what remains after fees.

Theo
Demo Day · stablesaver-web.vercel.app

Finding yield is easy.
Knowing what you're taking on is harder

WHAT YOU SEE

A big APY

One number on a dashboard, usually the highest one.

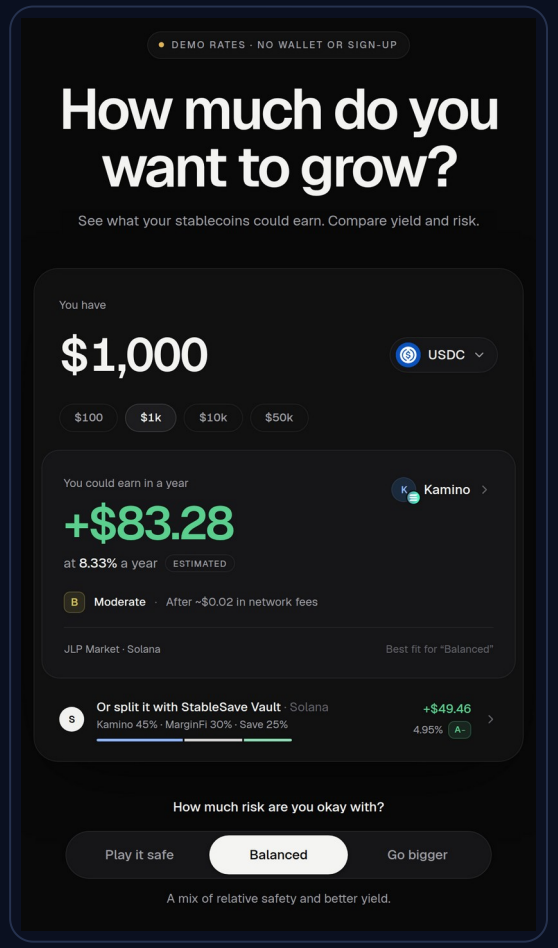

Conceptual illustration

WHAT YOU TAKE ON

Scattered	Options sit across many protocols and networks.
Higher isn't better	A higher APY can mean more risk, not a better deal.
Fees bite	Network fees can wipe out the return on a small deposit.
Hard to compare	Security, liquidity, maturity and strategy complexity hide in docs.
No framework	Beginners have no clear way to weigh any of it.

One place to compare yield, risk, and estimated net earnings

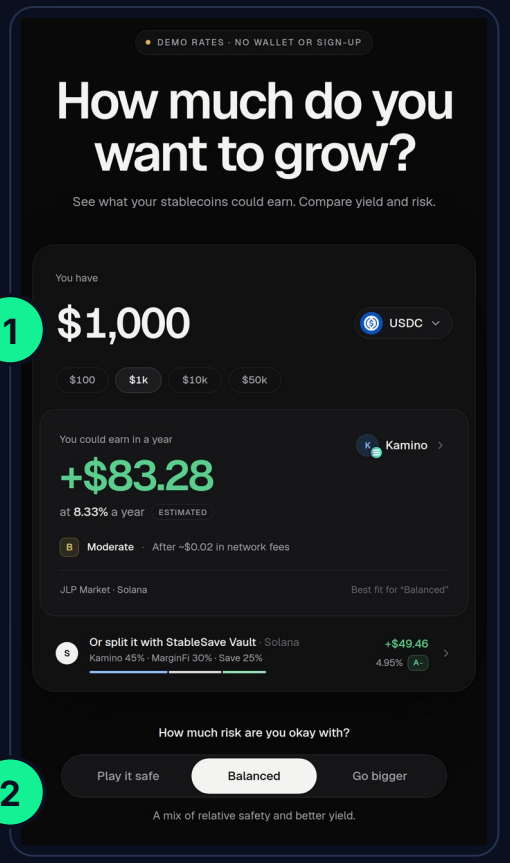

Real interface · local build, demo data

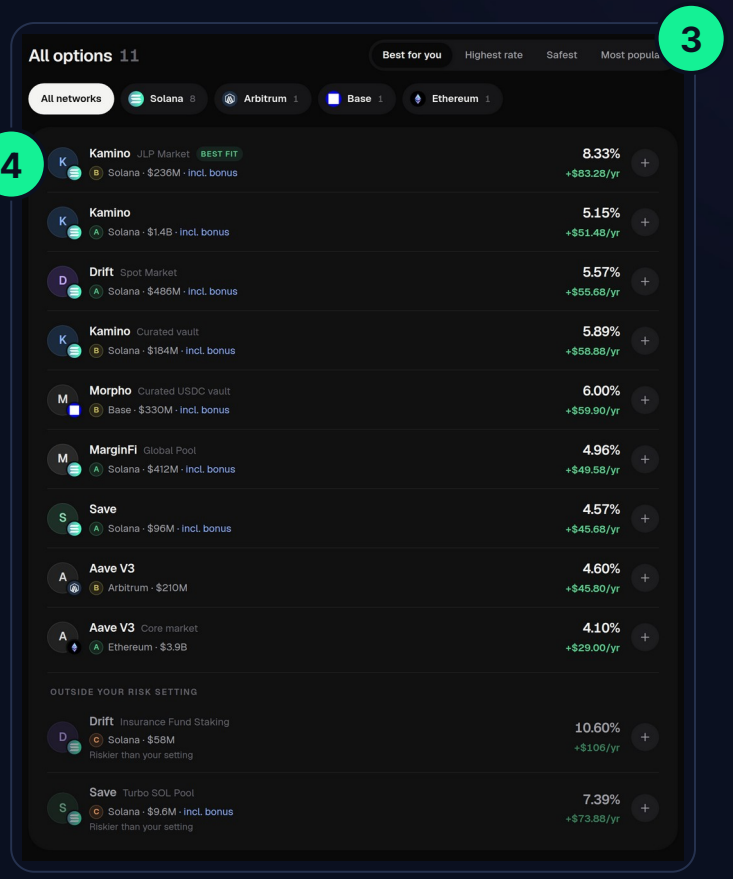

1. Enter a stablecoin amount
2. Pick a risk preference
3. Compare the options
4. Check the grade and its reasons
5. See earnings after fees
6. Continue to the official app

No wallet or sign-up
Comparing needs nothing but an amount.

Never holds your funds
You deposit from your own wallet, on the protocol's own app.

From a balance to a more informed decision

1. **Amount**
   $1,000 of USDC here
2. **Risk preference**
   Safe, Balanced or Bigger
3. **Ranked options**
   Sort: best fit, rate, safety
4. **A–D grade**
   Next to network, deposits
5. **Rate history**
   30 or 90 days, daily
6. **After fees**
   What you'd keep a year

Worked example (demo data): $1,000 USDC, Balanced → 8.33% → **about +$83 a year after fees**. Estimated, not promised.

A high APY should never tell the whole story

Nine factors, weighted (% of the score)

HOW THE SCORE IS BUILT

Score = 75% weighted average + 25% weakest factor

So one bad area pulls the grade down.

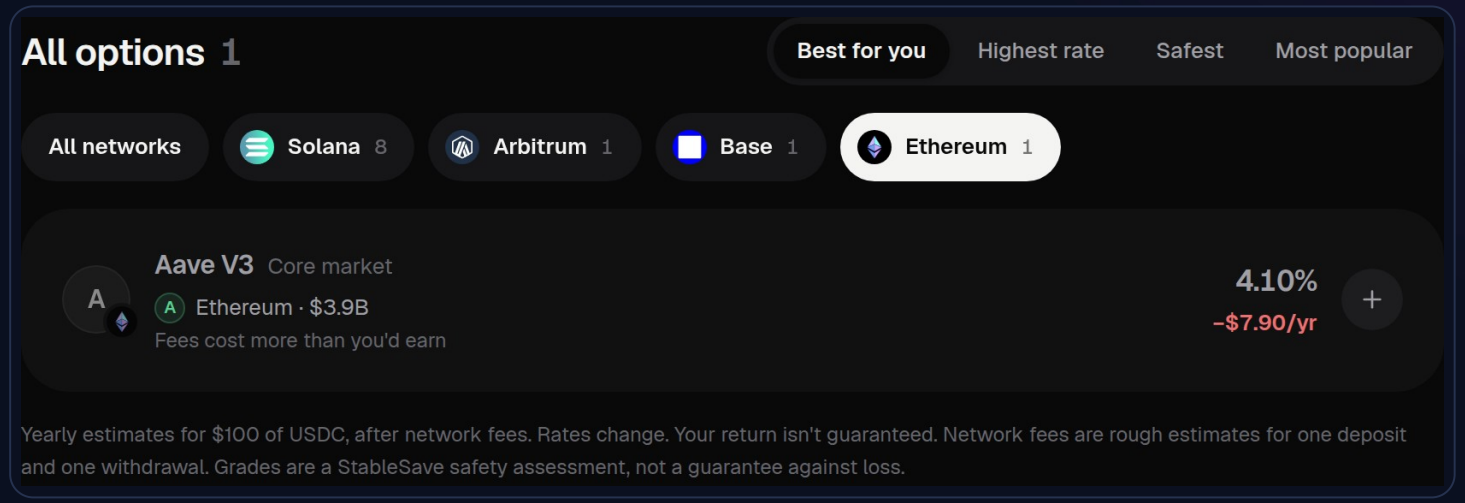

A	B	C	D
80+	65–79	50–64	<50

ONE WEAK FACTOR (DEMO DATA)

Kamino JLP Market: weighted average **81** (an A on its own). Concentration scores **37**, so the final score is **70: grade B**.

Hard caps can override the score (e.g. no public audits: at most C). Inputs the data doesn't cover are marked "Not verified" and scored cautiously, never guessed.

The return that matters is the return after costs

Real interface · local build, demo data · $100 of USDC, Ethereum

MARKED, NOT HIDDEN

$100 at 4.10% earns about $4.10 a year. Getting in and out of Ethereum is estimated at $12. **So the app says: "Fees cost more than you'd earn."**

	Headline rate	A year's interest	Network fees (est.)	What you keep
Ethereum	4.10%	$4.10	−$12.00	**−$7.90**
Solana	4.10%	$4.10	−$0.02	**+$4.08**

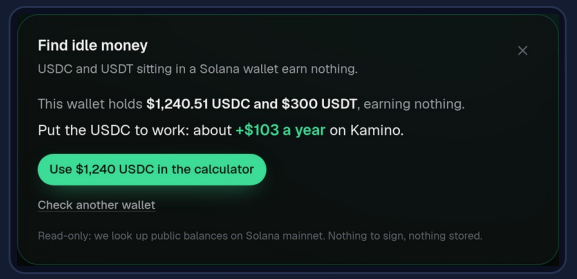

Illustrative: $100 at the same 4.10% rate, using StableSave's per-network fee estimates for one deposit and one withdrawal. Estimates, not live gas prices.

Four more questions answered before you deposit

FIND IDLE MONEY

Is money sitting idle in my wallet?

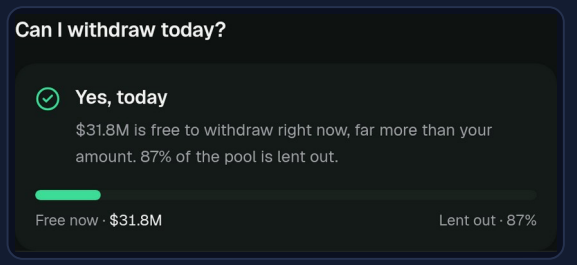

Paste any Solana address: read-only, and it fills the calculator.

CAN I WITHDRAW TODAY?

Can I get my money out today?

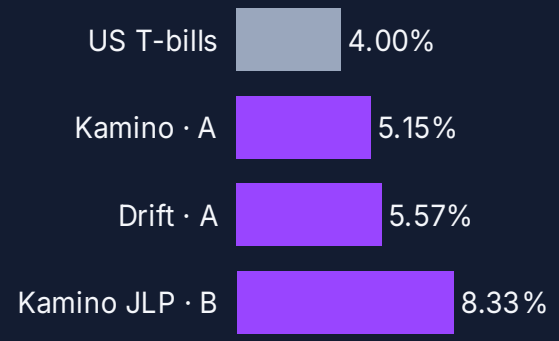

Cash free in the lending pool right now, versus your amount.

US T-BILL COMPARISON

Is it worth the crypto risk?

Every list starts with US Treasury bills, from the Treasury's own data.

SHARE MY ESTIMATE

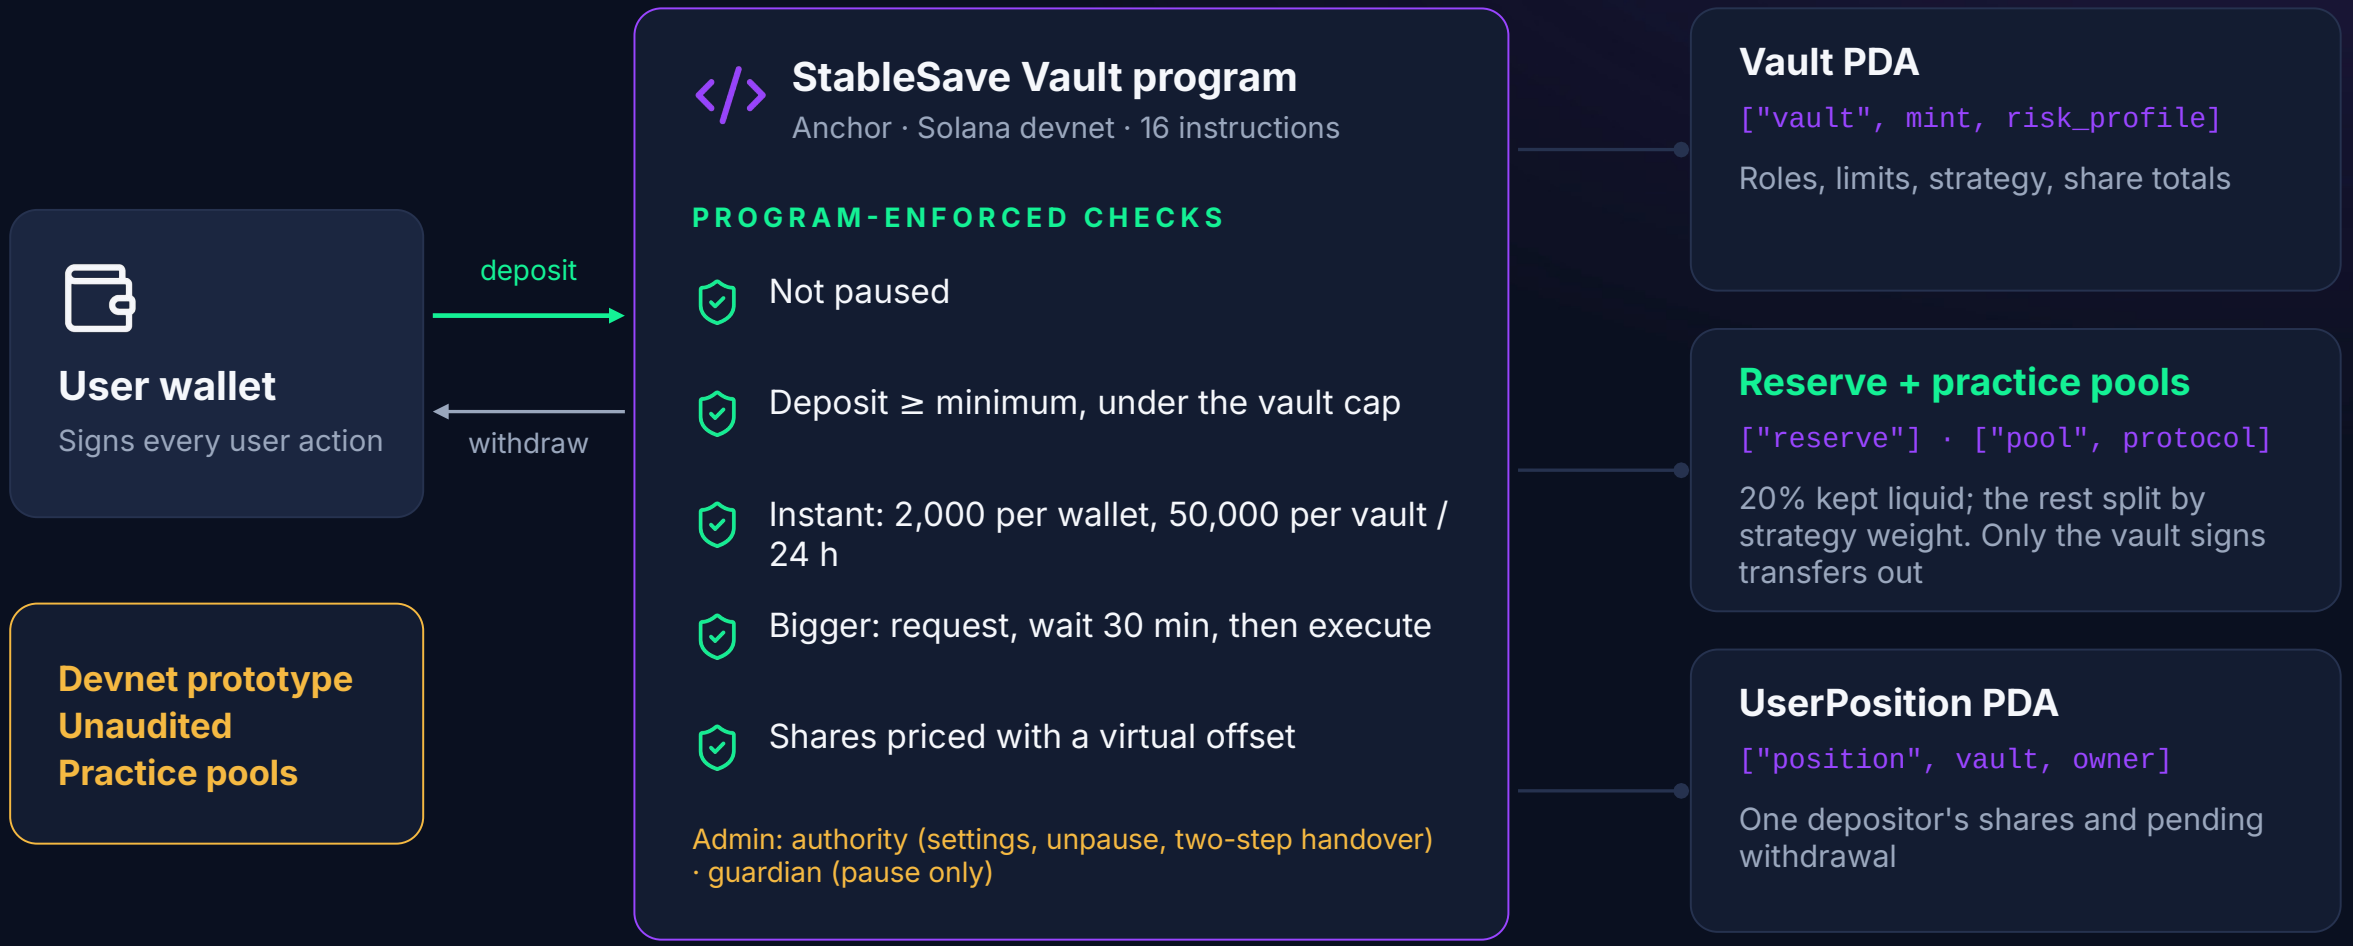

Can I show someone?

One click copies a link that previews as this card.

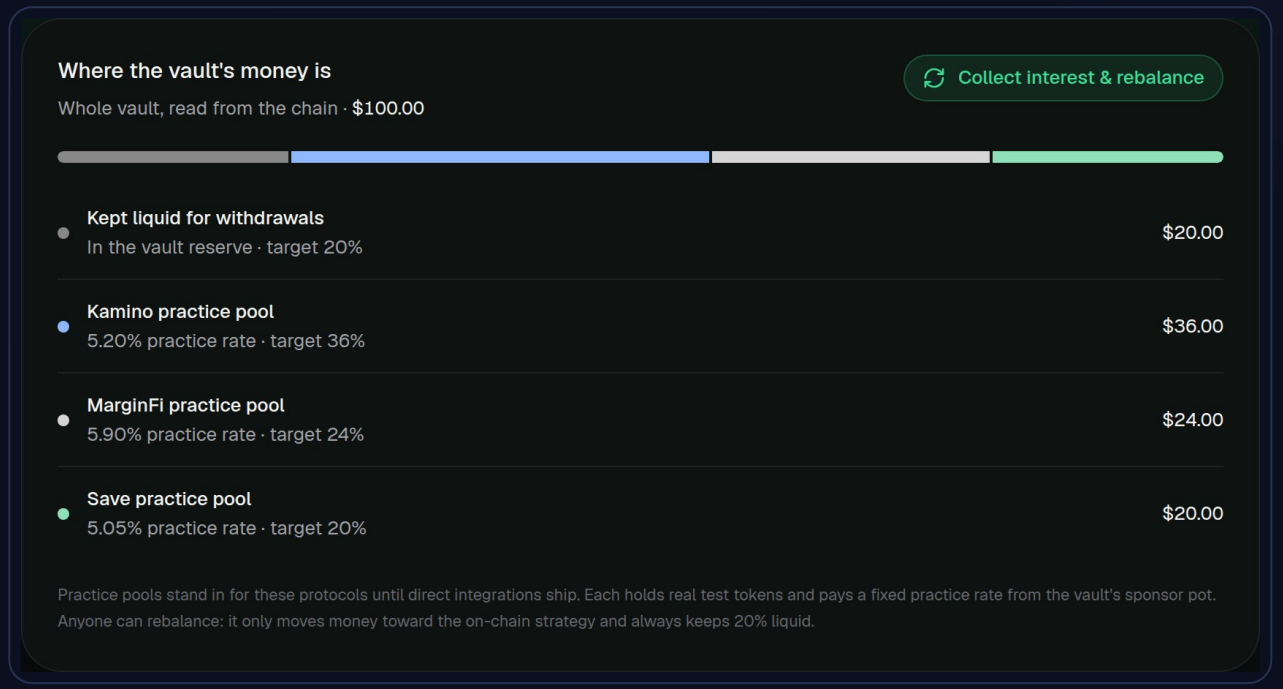

Real interface · local build, demo data · the wallet scan used a stand-in balance

A separate Anchor vault prototype brings the project on-chain

The vault now splits every deposit, and a test proves it

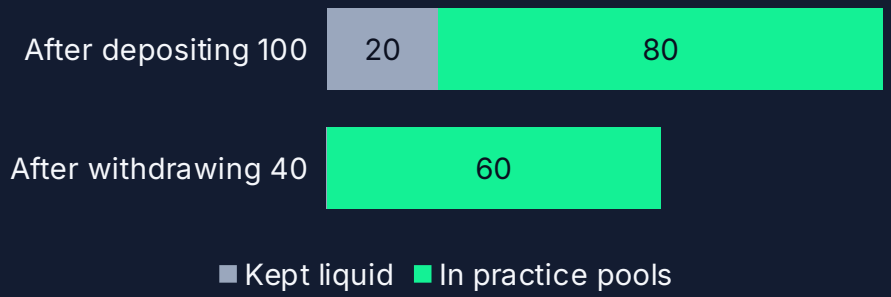

Real interface · local build · the pools card shows the rehearsal's split

CHECKED ON EVERY CHANGE

A real deposit and withdrawal on a local Solana validator, in GitHub Actions (test USDC)

Split by strategy
80 into three pools, 20 kept liquid

Pools top up withdrawals
The 20 short came back from the pools

The books match
Wallet 940 and pools 60, read on-chain

Security is not a badge. It is a set of explicit trade-offs

On-chain checks
Pause, minimum and cap
Rejects bad deposits and exits

2,000 per wallet / 24 h
Instant withdrawal limit
Limits a stolen wallet

50,000 per vault / 24 h
Instant limit, all users
Slows a bank run

30-minute timelock
Above the instant limits
Time to react; big exits wait

Guardian pause
Only the authority unpauses
Fast stop; no escape hatch yet

Role-based admin
Two-step authority handover
One powerful key today

Virtual share offset
1,000 shares, 1 asset
Stops share-price inflation

Automated tests
14 unit + 10 integration
Plus a local deploy rehearsal

Not yet: audit · multisig authority · strategy-change delay · pause escape hatch · fuzz testing (everything above runs on devnet only)

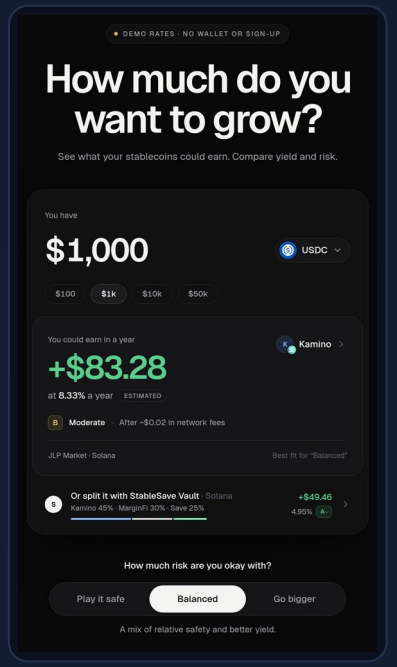

Let's see what works today

A · LIVE

Comparison app

stablesaver-web.vercel.app

1. Find idle money in a wallet
2. Switch Safe / Balanced / Bigger
3. Open an option: grade, withdraw
4. Compare with US T-bills
5. $100 + Ethereum: fees win
6. Share my estimate

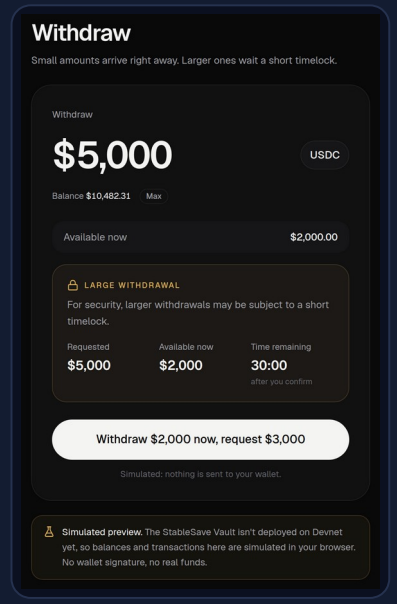

B · DEVNET PROTOTYPE

Vault

Wallet on Solana devnet

1. Connect a devnet wallet
2. Deposit: split into pools
3. Where the money is
4. Collect interest, rebalance
5. Withdraw: pools top up
6. Deposit from a Blink

Devnet tokens have no value. Practice pools pay fixed practice rates, not market yield. Thumbnails: local build (demo data; vault in simulated preview).

What is live, what is experimental, and what comes next

Live

- Stablecoin opportunity comparison
- Risk grades and explanations
- Fee-adjusted earnings estimates
- Withdraw-today check, T-bill comparison
- Idle-money scan and share cards

Devnet prototype

- Anchor vault program
- Deposits, shares, limits, timelock
- Split into practice pools on-chain
- Deposit Blink (Solana Action)
- Pause and authority controls

Not yet implemented

- CPI into Kamino, MarginFi, Drift and Save
- Market yield through the vault
- Production security assurances

ALSO WORTH KNOWING

One data source	Fixed network-fee estimates	Weights not back-tested
Ranks on today's APY, not the 30-day average	Bridge costs and risk not modelled	Admin and upgrade-key risk

From useful comparison tool to a more complete on-chain system

PHASE 1

Safety and correctness

- Escape hatch if a vault stays paused
- close_position to refund rent
- Fuzz the share math and limits

PHASE 2

Better recommendations

- Rank on the 30-day average APY
- Flag options that need funds moved between networks
- Back-test grades against past exploits

PHASE 3

Vault integration

- Swap a practice pool for one real Kamino strategy
- Tested against the real Kamino program on a local validator
- Same rebalance and on-chain balances

PHASE 4

Admin and expansion

- Multisig authority
- Delay on strategy changes
- Alerts, read-only portfolio, more tokens

PLANNED WORK

None of this is built yet. Safety first, then the feature that makes the vault real.

StableSave

Make stablecoin yield easier to understand before making it easier to chase.

Simpler comparison
Yield options in one place, ranked for your risk.

Risk grades that show trade-offs
A–D, with the reasons, and unknowns never guessed.

A separate Solana vault prototype
Controlled deposits and withdrawals on devnet.

Try it now
stablesaver-web.vercel.app

Feedback welcome on risk scoring, vault security, and which integration to build next.
